YAML Syntax ¶

This page provides a basic overview of correct YAML syntax, which is how Ansible playbooks (our configuration management language) are expressed.

We use YAML because it is easier for humans to read and write than other common data formats like XML or JSON. Further, there are libraries available in most programming languages for working with YAML.

You may also wish to read [Playbooks \(playbooks.html\)](#) at the same time to see how this is used in practice.

YAML Basics

For Ansible, nearly every YAML file starts with a list. Each item in the list is a list of key/value pairs, commonly called a “hash” or a “dictionary”. So, we need to know how to write lists and dictionaries in YAML.

There’s another small quirk to YAML. All YAML files (regardless of their association with Ansible or not) can optionally begin with `---` and end with `...`. This is part of the YAML format and indicates the start and end of a document.

All members of a list are lines beginning at the same indentation level starting with a `"- "` (a dash and a space):

```
---  
# A list of tasty fruits  
fruits:  
  - Apple  
  - Orange  
  - Strawberry  
  - Mango  
...
```

A dictionary is represented in a simple `key: value` form (the colon must be followed by a space):

```
# An employee record  
martin:  
  name: Martin D'vloper  
  job: Developer  
  skill: Elite
```

More complicated data structures are possible, such as lists of dictionaries, dictionaries whose values are lists or a mix of both:

```
# Employee records
- martin:
  name: Martin D'vloper
  job: Developer
  skills:
    - python
    - perl
    - pascal
- tabitha:
  name: Tabitha Bitumen
  job: Developer
  skills:
    - lisp
    - fortran
    - erlang
```

Dictionaries and lists can also be represented in an abbreviated form if you really want to:

```
---
martin: {name: Martin D'vloper, job: Developer, skill: Elite}
fruits: ['Apple', 'Orange', 'Strawberry', 'Mango']
```

Ansible doesn't really use these too much, but you can also specify a boolean value (true/false) in several forms:

```
create_key: yes
needs_agent: no
knows_oop: True
likes_emacs: TRUE
uses_cvs: false
```

Values can span multiple lines using `|` or `>`. Spanning multiple lines using a `|` will include the newlines. Using a `>` will ignore newlines; it's used to make what would otherwise be a very long line easier to read and edit. In either case the indentation will be ignored. Examples are:

```
include_newlines: |
    exactly as you see
    will appear these three
    lines of poetry

ignore_newlines: >
    this is really a
    single line of text
    despite appearances
```

Let's combine what we learned so far in an arbitrary YAML example. This really has nothing to do with Ansible, but will give you a feel for the format:

```
---
# An employee record
name: Martin D'vloper
job: Developer
skill: Elite
employed: True
foods:
  - Apple
  - Orange
  - Strawberry
  - Mango
languages:
  perl: Elite
  python: Elite
  pascal: Lame
education: |
  4 GCSEs
  3 A-Levels
  BSc in the Internet of Things
```

That's all you really need to know about YAML to start writing *Ansible* playbooks.

Gotchas

While YAML is generally friendly, the following is going to result in a YAML syntax error:

```
foo: somebody said I should put a colon here: so I did

windows_drive: c:
```

...but this will work:

```
windows_path: c:\windows
```

You will want to quote hash values using colons followed by a space or the end of the line:

```
foo: "somebody said I should put a colon here: so I did"

windows_drive: "c:"
```

...and then the colon will be preserved.

Further, Ansible uses “`{{ var }}`” for variables. If a value after a colon starts with a “`{`”, YAML will think it is a dictionary, so you must quote it, like so:

```
foo: "{{ variable }}"
```

If your value starts with a quote the entire value must be quoted, not just part of it. Here are some additional examples of how to properly quote things:

```
foo: "{{ variable }}/additional/string/literal"  
foo2: "{{ variable }}"\\backslashes\\are\\also\\special\\characters"  
foo3: "even if it's just a string literal it must all be quoted"
```

Not valid:

```
foo: "E:\\path\\"rest\\of\\path"
```

The same applies for strings that start or contain any YAML special characters `[] { } : > |`.

Boolean conversion is helpful, but this can be a problem when you want a literal `yes` or other boolean values as a string. In these cases just use quotes:

```
non_boolean: "yes"  
other_string: "False"
```

YAML converts certain strings into floating-point values, such as the string *1.0*. If you need to specify a version number (in a requirements.yml file, for example), you will need to quote the value if it looks like a floating-point value:

```
version: "1.0"
```
